Scenario

You are a cybersecurity analyst for yummyrecipesforme.com, a website that sells recipes and cookbooks. A former employee has decided to lure users to a fake website with malware.

The baker executed a brute force attack to gain access to the web host. They repeatedly entered several known default passwords for the administrative account until they correctly guessed the right one. After they obtained the login credentials, they were able to access the admin panel and change the website's source code. They embedded a javascript function in the source code that prompted visitors to download and run a file upon visiting the website. After embedding the malware, the baker changed the password to the administrative account. When customers download the file, they are redirected to a fake version of the website that contains the malware.

Several hours after the attack, multiple customers emailed yummyrecipesforme's helpdesk. They complained that the company's website had prompted them to download a file to access free recipes. The customers claimed that, after running the file, the address of the website changed and their personal computers began running more slowly.

In response to this incident, the website owner tries to log in to the admin panel but is unable to, so they reach out to the website hosting provider. You and other cybersecurity analysts are tasked with investigating this security event.

To address the incident, you create a sandbox environment to observe the suspicious website behavior. You run the network protocol analyzer tcpdump, then type in the URL for the website, yummyrecipesforme.com. As soon as the website loads, you are prompted to download an executable file to update your browser. You accept the download and allow the file to run. You then observe that your browser redirects you to a different URL, greatrecipesforme.com, which contains the malware.

The logs show the following process:

1. The browser initiates a DNS request: It requests the IP address of the yummyrecipesforme.com URL from the DNS server.
2. The DNS replies with the correct IP address.
3. The browser initiates an HTTP request: It requests the yummyrecipesforme.com webpage using the IP address sent by the DNS server.
4. The browser initiates the download of the malware.
5. The browser initiates a DNS request for greatrecipesforme.com.
6. The DNS server responds with the IP address for greatrecipesforme.com.
7. The browser initiates an HTTP request to the IP address for greatrecipesforme.com.

A senior analyst confirms that the website was compromised. The analyst checks the source code for the website. They notice that javascript code had been added to prompt website visitors to download an executable file. Analysis of the downloaded file found a script that redirects the visitors' browsers from yummyrecipesforme.com to greatrecipesforme.com.

The cybersecurity team reports that the web server was impacted by a brute force attack. The disgruntled baker was able to guess the password easily because the admin password was still set to the default password. Additionally, there were no controls in place to prevent a brute force attack.

Your job is to document the incident in detail, including identifying the network protocols used to establish the connection between the user and the website. You should also recommend a security action to take to prevent brute force attacks in the future.

Security incident report

Section 1: Identify the network protocol involved in the incident
DNS(domain system names) -> Resolves domain names to IP addresses HTTP(hypertext transfer protocol)-> transferring from page to page on the internet TCP (Transmission Control Protocol) -> establishes connection and reliable connection between devices

Section 2: Document the incident
Incident Overview: ● **Date/Time:** Multiple customer complaints started several hours after the attack. ● **Affected Entity:** yummyrecipesforme.com ● **Type of Attack:** Brute force attack leading to website compromise. ● **Attacker:** Disgruntled former employee (referred to as "the baker"). **incident Details:** 1. **Initial Compromise:** ○ The attacker executed a brute force attack against the administrative account of the website's web host. ○ Default passwords were used, and the correct one was eventually guessed, granting access to the admin panel. 2. **Modification of Website Code:** ○ The attacker embedded a malicious JavaScript function in the website’s source code. ○ This script prompted visitors to download an executable file upon visiting the site. 3. **Malware Deployment:** ○ The downloaded file contained a script that redirected users from yummyrecipesforme.com to a malicious site, greatrecipesforme.com. ○ The redirection led to slow computer performance and potential further infection.

4. **Customer Complaints:**
    - Customers reported being prompted to download a file and subsequent redirection to a different website.
    - Issues included slow computer performance after running the file.
5. **Investigation Findings:**
    - DNS and HTTP requests were logged, showing the flow from the initial site to the malicious site.
    - Analysis confirmed the addition of malicious JavaScript and the presence of the redirect script in the downloaded file.
    - The administrative password had been changed by the attacker post-compromise.

Section 3: Recommend one remediation for brute force attacks

Recommendation: Implement Multi-Factor Authentication (MFA)

- **Description:** Require an additional verification step beyond just the password. This could be a code sent to a mobile device, an email verification, or a hardware token.

Significantly increases the difficulty for attackers to gain unauthorized access, even if they manage to guess the password.

Provides an extra layer of security, making brute force attacks less effective.
